

Project Vynix: Decoupled Human-Object Interaction Detection via 3-Stream Spatial-Visual Adaptation and Continuous Geometric Hallucination Veto

A Computationally Efficient, Physically Grounded Framework for Resolving Spatial Hallucinations and Long-Tail Gradient Starvation on HICO-DET

Jatin Deswal, Akarshit Garg, Ayush Sharma

Department of Computer Science and Engineering, Project Vynix Research

Abstract—Human-Object Interaction (HOI) detection requires simultaneously localizing human agents, object instances, and classifying their interactive semantic predicates. Contemporary state-of-the-art (SOTA) architectures on the benchmark HICO-DET dataset rely almost exclusively on end-to-end DETR-based Transformers or massive foundation vision-language models (VLMs) that require dense backpropagation across all 38,118 training images for 40 to 140 GPU-hours. In addition to high computational demands, these approaches suffer from catastrophic gradient starvation on the 155 long-tail “Rare” interaction categories and exhibit frequent spatial hallucinations—predicting physical contact interactions when human and object entities are separated by wide spatial distances. In this paper, we introduce **Project Vynix**, a decoupled, compute-efficient framework comprising: (1) a real-time anchor-free YOLOv8 detector, (2) a 3-Stream multi-crop visual representation fusing human, object, and union visual features with a frozen CLIP ViT-B/16 backbone, (3) a continuous 8-dimensional normalized spatial geometry MLP, (4) a continuous Gaussian-attenuated geometric veto gate that dynamically suppresses physically ungrounded contact hypotheses, and (5) a non-parametric exemplar memory cache for rapid residual adaptation. Without observing any training images (zero-shot), Vynix attains **22.17% mAP** on HICO-DET while vetoing **319,803 spatial hallucinations**. When trained offline across all 38,118 training images and evaluated end-to-end on the complete official test set of **9,658 images**, Vynix achieves **30.31% Full mAP**, **29.71% Rare mAP**, and **30.51% Non-Rare mAP**, triggering **265,189 geometric vetoes** and rescuing **54,532** true contact interactions missed by naive binary thresholds. Vynix trains in only **17.33 minutes on a single commodity GPU** (0.29 GPU-hours), demonstrating an unprecedented Pareto frontier in computational efficiency, physical groundedness, and long-tail performance parity.

Index Terms—Human-Object Interaction, Vision-Language Models, Decoupled Architectures, Spatial Geometry, Hallucination Suppression, Long-Tail Learning, Compute Efficiency.

I. INTRODUCTION

Human-Object Interaction (HOI) detection is a core computer vision task essential for embodied artificial intelligence, autonomous robotics, assistive human-computer interaction, and intelligent video surveillance [1], [2]. The task requires detecting human-object bounding box pairs and classifying the active relational verb predicates linking them, formalized as structured triplets $\langle \text{human}, \text{predicate}, \text{object} \rangle$.

Despite significant empirical progress over recent years, contemporary HOI architectures continue to grapple with three fundamental bottlenecks:

1) Spatial Blindness and Hallucinations: Large pretrained Vision-Language Models (VLMs), such as CLIP [16], align global image-level tokens with textual prompts. However, they lack explicit inductive geometric priors. In cluttered multi-agent scenes, VLMs frequently hallucinate physical contact (e.g., predicting *holding cup* or *riding bicycle*) for humans who are merely co-present in the scene but separated by large spatial distances.

2) Long-Tail Gradient Starvation: Standard benchmarks like HICO-DET [15] exhibit an extreme long-tail distribution across 600 HOI categories. Fully supervised DETR-based detectors (e.g., QPIC [7], CDN [8]) are trained with joint cross-entropy loss, where dominant head categories (*hold phone*, *sit on chair*) dominate gradient updates, severely starving the 155 Rare classes (<10 training samples). As a result, QPIC drops from 31.23% on Non-Rare classes to 21.85% on Rare classes.

3) Prohibitive Compute Hunger: Leading generative and transformer-based methods (e.g., DiffHOI [13], ADA-CM [14]) require full training on all 38,118 images of HICO-DET across 80–140 GPU-hours on multi-GPU server clusters, creating substantial barriers for edge deployment and fast adaptation.

To overcome these challenges, we present **Project Vynix**, a decoupled framework that unites anchor-free real-time object detection with explicit continuous geometric reasoning and non-parametric exemplar caching.

Our core architectural philosophy is that visual appearance and spatial configuration should be modeled through distinct representations and harmonized via physical constraints. Specifically, we extract a 3-Stream visual embedding (human, object, and union contexts) using a frozen CLIP ViT-B/16 backbone, coupled with an 8-dimensional normalized spatial geometry vector processed by a dedicated MLP. To eradicate spatial hallucinations while preserving edge-contact actions, we introduce a **Soft Continuous Geometric Veto Gate**, which dynamically dampens predicted contact predicates via a Gaussian distance attenuation function whenever physical separation exceeds normal contact bounds. Finally, we formulate a non-parametric exemplar cache that stores support features per interaction class, completely preserving rare class discriminability.

The primary contributions of this paper are:

- We design **Vynix-Adapter-3S**, a decoupled HOI architecture combining YOLOv8-medium, a frozen 3-Stream CLIP ViT-B/16 visual encoder, and an 8D spatial geometry MLP, enabling end-to-end inference without backbone fine-tuning.
- We propose a **Soft Continuous Geometric Veto Gate** that suppresses 265,189 false positive spatial hallucinations on the 9,658 HICO-DET test images, while smoothly recovering 54,532 border-touching interactions that rigid binary thresholds discarded.

- We establish near-perfect **Rare vs. Non-Rare class parity** (29.71% vs. 30.51%), effectively eliminating the long-tail gradient starvation bottleneck.

- Rigorous experiments on all 9,658 test images demonstrate that Vynix achieves **30.31% Full mAP** while training in only **17.33 minutes on a single commodity GPU** (0.29 GPU-hours), representing a $\$300\times\$$ to $\$500\times\$$ reduction in training compute compared to leading DETR and diffusion models.

II. RELATED WORK

A. Two-Stage CNN-Based HOI Detectors

Early deep HOI detection methods employed two-stage sequential pipelines. Methods such as iCAN [1] used Faster R-CNN to generate candidate bounding boxes and extracted contextual visual cues using spatial attention maps. TIN [2] introduced an interactiveness network to filter non-interacting pairs. VSGNet [3] utilized spatial graph convolution to model inter-node visual relationships. PPDM [4] reframed interaction detection as a parallel point matching problem. While pioneering, two-stage CNNs suffered from quadratic proposal explosion and achieved moderate mAP scores between 14% and 22%.

B. One-Stage Transformer and DETR-Based HOI

The emergence of DETECTION TRANSFORMER (DETR) motivated one-stage set-prediction architectures. HOTR [5] and QPIC [7] leveraged bipartite Hungarian matching and query-based cross-attention to predict interaction triplets directly. CDN [8] disentangled interactiveness classification from verb categorization. STIP [9] incorporated spatial interaction primitives. While these architectures advanced Full mAP to the 29–32% regime, their reliance on end-to-end backpropagation across 38,118 images led to severe overfitting on Rare classes and high computational requirements (60–80 GPU-hours).

C. Vision-Language Models and Decoupled Adapters

To alleviate semantic sparsity, recent works transfer knowledge from pretrained Vision-Language Models (VLMs). GEN-VLKT [10] distilled multimodal knowledge from CLIP into visual relation queries. HOI-CLIP [11] and ViPLO [12] adapted CLIP visual features via visual prompts and line-prompt tokens. DiffHOI [13] integrated generative diffusion priors from Stable Diffusion, reaching 41.50% mAP at the expense of 120 GPU-hours. Most recently, ADA-CM [14] introduced adaptive cross-modal context modeling with a Swin-Large backbone, attaining 43.20% mAP over 140 GPU-hours. In contrast, Vynix achieves competitive performance with a $\$300\times\$$ reduction in training compute by decoupling geometric validation from visual classification.

III. PROPOSED METHODOLOGY: PROJECT VYNIX

A. Pipeline Overview and Problem Formulation

Given an input RGB image $I \in \mathbb{R}^{H \times W \times 3}$, our objective is to output a set of detected interaction triplets $\mathcal{Y} = \{ \angle b_h, b_o, a \}_{m=1}^M$, where $b_h = (x_1, y_1, x_2, y_2) \in \mathbb{R}^4$ denotes the human bounding box, $b_o \in \mathbb{R}^4$ denotes the object bounding box with object class $c_o \in \{1, \dots, 80\}$, and $a \in \{1, \dots, 117\}$ represents the verb predicate. The complete interaction class $k \in \{1, \dots, 600\}$ uniquely pairs an object c_o with a verb a .

B. Entity Localization (“The Eyes”)

Candidate human and object proposals are generated using YOLOv8-medium:

$$\mathcal{S}(b_h, s_h), \mathcal{S}(b_o, s_o, c_o) = \text{YOLOv8}(I) \quad (1)$$

where $s_h, s_o \in [0, 1]$ represent detection confidence scores. To maintain high recall for long-tail occluded objects, detection thresholding is applied at $s_h \geq 0.08, s_o \geq 0.08$. All valid $\mathcal{S}(b_h, b_o)$ candidate pairs form proposal set $\mathcal{P}$. Pairs are prioritized by joint confidence $s_h \cdot s_o$.

C. 3-Stream Multi-Crop Visual Encoding

For each candidate pair $(b_h, b_o) \in \mathcal{P}$, we compute the minimum bounding box encompassing both entities (the union crop $b_u = b_h \cup b_o$). Rather than relying solely on the union region, we feed three distinct image crops into a frozen CLIP ViT-B/16 image encoder $\mathcal{E}_v$:

$$\begin{aligned} f_h &= \mathcal{E}_v(\text{crop}(I, b_h)), \quad f_o = \\ &= \mathcal{E}_v(\text{crop}(I, b_o)), \quad f_u = \\ &= \mathcal{E}_v(\text{crop}(I, b_u)) \end{aligned} \quad (2)$$

where $f_h, f_o, f_u \in \mathbb{R}^{512}$ are ℓ_2 -normalized feature vectors. The 3-Stream visual representation f_v is constructed via linear projection and concatenation:

$$f_v = \text{LayerNorm}(\left(W_h f_h + W_o f_o + W_u f_u \right)) \quad (3)$$

By employing ViT-B/16 with $14 \times 14 = 196$ spatial patch tokens (a $4\times$ token density increase over ViT-B/32’s 49 patches), subtle human hand-object contact interfaces are preserved alongside global contextual semantics.

D. Continuous 8D Spatial Geometry MLP (“The Brain”)

To explicitly model the relative spatial configuration of human and object, we construct an 8-dimensional scale- and translation-invariant geometric descriptor $g(b_h, b_o) \in \mathbb{R}^8$:

$$\begin{aligned} g &= \left[\frac{x_o^c - x_h^c}{w_h}, \frac{y_o^c - y_h^c}{h_h}, \frac{w_o}{w_h}, \frac{h_o}{h_h}, \text{IoU}, d_{\text{norm}}, \theta_{ho}, \ln \left(\frac{A_h}{A_o} \right) \right] \end{aligned} \quad (4)$$

where (x^c, y^c) are box centroids, d_{norm} is normalized Euclidean centroid distance, θ_{ho} is relative polar angle, and $\ln(A_h / A_o)$ captures logarithmic area ratio. The descriptor g is projected through a 2-layer MLP with GELU activations: $f_{\text{geom}} = \text{MLP}_g(g) \in \mathbb{R}^{256}$.

E. Soft Continuous Geometric Veto Gate (“The Arbiter”)

Standard VLMs lack geometric verification: if a person and an airplane appear in the same frame, CLIP assigns high semantic affinity to *board airplane* even when separated by hundreds of meters.

Let $\mathcal{V}_{\text{contact}}$ denote physical contact predicates (e.g., *hold*, *ride*, *sit on*, *eat*, *carry*) requiring spatial adjacency. In contrast to naive binary thresholds ($\text{IoU} > 0$) that trigger a catastrophic cliff at box boundaries, we formulate the **Soft Continuous Geometric Veto Gate**:

$$\begin{aligned} g(v, \text{IoU}, d_{\text{box}}) &= \begin{cases} 1.0, & \text{if } v \in \mathcal{V}_{\text{contact}} \text{ or } \text{IoU} > 0 \\ \exp\left(-\frac{d_{\text{box}}^2}{2\sigma^2}\right), & \text{if } \end{cases} \end{aligned}$$

$$\forall \mathcal{V}_{\text{contact}} \wedge \text{IoU} = 0 \quad (5)$$

where d_{box} denotes the normalized Euclidean distance between the nearest edges of b_h and b_o , and $\sigma = 0.08$. As illustrated in Fig. 2, adjacent contact pairs ($d_{\text{box}} \approx 0.01$) retain a multiplier of 0.98, while distant false alarms ($d_{\text{box}} > 0.25$) asymptotically decay to zero. Across the test set, this formulation vetoed 265,189 invalid hypotheses while rescuing 54,532 genuine interactions.

F. Non-Parametric Memory Cache & Residual Blending

To retain fine-grained prototype representations without extensive backpropagation, we construct a non-parametric exemplar memory cache. Key features $k_e = [f_v; f_{\text{geom}}]$ in

$\mathbb{R}^{768}$ and labels $v_e \in \{0, 1\}^{600}$ form support matrices K_{cache} and V_{cache} .

For query feature q , affinities are evaluated with temperature scale β :

$$A = \exp\left(-\beta \cdot (1 - q \cdot K_{\text{cache}}^T)\right)$$

The cache prediction is $S_{\text{cache}} = A \cdot V_{\text{cache}}$. The final HOI triplet confidence is formulated as a residual blend:

$$S_{\text{HOI}}(b_h, b_o, k) = s_h \cdot s_o \cdot g(v, d_{\text{box}}) \cdot \left[(1 - \alpha) S_{\text{vlm}}(k) + \alpha S_{\text{cache}}(k) \right] \quad (7)$$

where $\alpha = 0.35$ and $\beta = 5.5$. Because K_{cache} is non-parametric, rare class prototypes remain strictly preserved without gradient degradation from head classes.

TABLE I: STATE-OF-THE-ART COMPARATIVE EVALUATION ON THE HICO-DET BENCHMARK (DEFAULT SETTING)

Empirical metrics across 14 milestone published research papers (2018–2024) vs. Project Vynix variants evaluated on the full test set (9,658 images). Training image counts and GPU compute hours are reported.

Method	Venue	Supervision Paradigm	Backbone	Train Images	GPU Hours	Full mAP	Rare mAP	Non-Rare mAP

IV. EXPERIMENTAL EVALUATION

A. Benchmark Dataset & Implementation Details

Dataset: We evaluate on the official HICO-DET benchmark [15], containing 38,118 training images and 9,658 test images across 600 HOI categories (80 COCO objects and 117 verb predicates). Categories are partitioned into Full (600), Rare (155, <10 training instances), and Non-Rare (445, ≥ 10 instances).

Evaluation Protocol: We compute Mean Average Precision (mAP) under the standard Default setting, requiring human and

object box $\text{IoU} \geq 0.5$ with ground truth. In our flagship evaluation on all 9,658 test images, 265,189 spatial hallucinations were suppressed, yielding verified scores of **30.31% Full mAP**, **29.71% Rare mAP**, and **30.51% Non-Rare mAP**.

Hardware and Environment: All training runs were conducted on a single commodity GPU environment (NVIDIA RTX 3050 Ti Laptop / T4 GPU). Offline feature caching and adapter training completed in just **17.33 minutes (0.29 GPU-hours)**, demonstrating extreme computational efficiency without distributed clusters.

Fig. 2. Physical-Semantic Soft Continuous Geometric Veto Gate. Comparison of the rigid binary cliff ($\text{IoU}=0 \rightarrow \text{rightarrow } 0$) against the continuous Gaussian distance attenuation curve ($G(v, \text{IoU}, d_{\text{box}})$), rescuing 54,532 border-touching interactions.

B. Main Benchmark Results

As detailed in Table I, Vynix Flagship achieves **30.31% Full mAP**, outperforming seminal one-stage DETR models such as QPIC (29.07%) and classical two-stage CNNs (iCAN 14.84%, TIN 17.03%, VSGNet 19.80%, PPDM 21.73%), while approaching complex transformer architectures.

Crucially, on the 155 Rare classes, Vynix achieves **29.71% mAP**, representing an advantage of **+7.86%** over QPIC (21.85%), **+19.26%** over iCAN (10.45%), and **+0.46%** over GEN-VLKT (29.25%).

Fig. 3. Detector capacity and vision backbone scaling progression: YOLOv8-nano baseline (22.03%) $\rightarrow$ YOLOv8-medium + Soft Gate (28.23%) $\rightarrow$ ViT-B/16 token density (30.31%).

C. Component Ablation Studies

To quantify the incremental impact of each component, we present systematic ablations on HICO-DET in Table II and Table III.

TABLE II: COMPONENT ABLATION STUDY ON HICO-DET

Configuration	Full mAP	Rare mAP	Vetoed Hallucinations
CLIP Baseline (Union Crop only)	16.40%	13.10%	0
+ Physical Geometric Veto Gate	20.85%	17.20%	319,803
+ 3-Stream Encoding ($f_h + f_o + f_u$)	22.17%	18.57%	319,803
+ Decoupled Geometry MLP + Memory Cache	26.15%	25.40%	319,803
+ Soft Continuous Geometric Gate	28.23%	28.98%	265,189
+ ViT-B/16 (196 Spatial Tokens, Flagship)	30.31%	29.71%	265,189

TABLE III: DETECTOR AND VISION TOKEN GRANULARITY ABLATION

Model Variant	Detector	Backbone	Gate	Full mAP	Rare mAP
Vynix-Base	YOLOv8n	ViT-B/32	Hard Binary	22.03%	23.32%
Vynix-M (Hard)	YOLOv8m	ViT-B/32	Hard Binary	26.15%	25.40%
Vynix-M (Soft)	YOLOv8m	ViT-B/32	Soft Continuous	28.23%	28.98%
Vynix-Flagship	YOLOv8m	ViT-B/16	Soft Continuous	30.31%	29.71%

Impact of Veto Gate: Applying the Veto Gate to the raw CLIP baseline increases mAP from 16.40% to 20.85% (+4.45%) and vetoes 319,803 false positive pairs. Top overridden verbs include *hold* (44,979 pairs), *carry* (31,730 pairs), and *wash* (27,652 pairs).

Impact of 3-Stream Crops: Adding separate human and object crops adds +1.32% mAP, resolving small objects that are lost in union downsampling.

Impact of ViT-B/16: Scaling from ViT-B/32 (49 patch tokens) to ViT-B/16 (196 patch tokens) increases Full mAP from 28.23% to 30.31% (+2.08%), demonstrating the critical importance of fine-grained spatial token granularity for resolving delicate interaction interfaces.

Fig. 4. Long-tail Rare vs. Non-Rare performance parity. Vynix achieves near parity between Rare (29.71%) and Non-Rare (30.51%), eliminating the severe degradation plaguing end-to-end DETRs.

Fig. 5. Computational and Data Efficiency Pareto Frontiers. *Left:* Training images required vs. Full mAP. *Right:* Training GPU-hours vs. Full mAP. Vynix demonstrates extreme Pareto dominance in training compute efficiency.

V. DISCUSSION AND LIMITATIONS

Primary Detector Occlusion: Heavy occlusion of small objects (e.g. phones in pockets, small utensils) bounds downstream recall, an inherent bottleneck inherited from the 2D bounding box detector.

Fine-Grained Interaction Ambiguity: Subtle actions sharing identical physical contact geometry (e.g., *inspect bicycle* vs. *repair bicycle*) remain challenging to distinguish from single static frames without temporal dynamics. Extending Vynix to video HOI is our primary future direction.

VI. CONCLUSION

Project Vynix introduces a decoupled, compute-efficient framework for Human-Object Interaction detection that couples real-time object detection with 3-Stream visual encoding, an 8D spatial geometry MLP, a soft continuous geometric veto gate, and non-parametric memory caching. Evaluated on all 9,658 official HICO-DET test images, Vynix achieves **30.31% Full mAP**, **29.71% Rare mAP**, and **30.51% Non-Rare mAP**, suppressing 265,189 spatial hallucinations and rescuing 54,532 border-touching interactions. By training in just 17.33 minutes on a single commodity GPU and overcoming long-tail gradient starvation, Vynix provides an accessible, grounded, and reproducible foundation for future interaction reasoning research.
